Learned Spring Framework to develop a healthcare project with scalable and organized architecture. Watched tutorials and videos to understand modules like Spring Core, Spring MVC, and Spring Boot. Applied the concepts practically to implement features in the healthcare application.

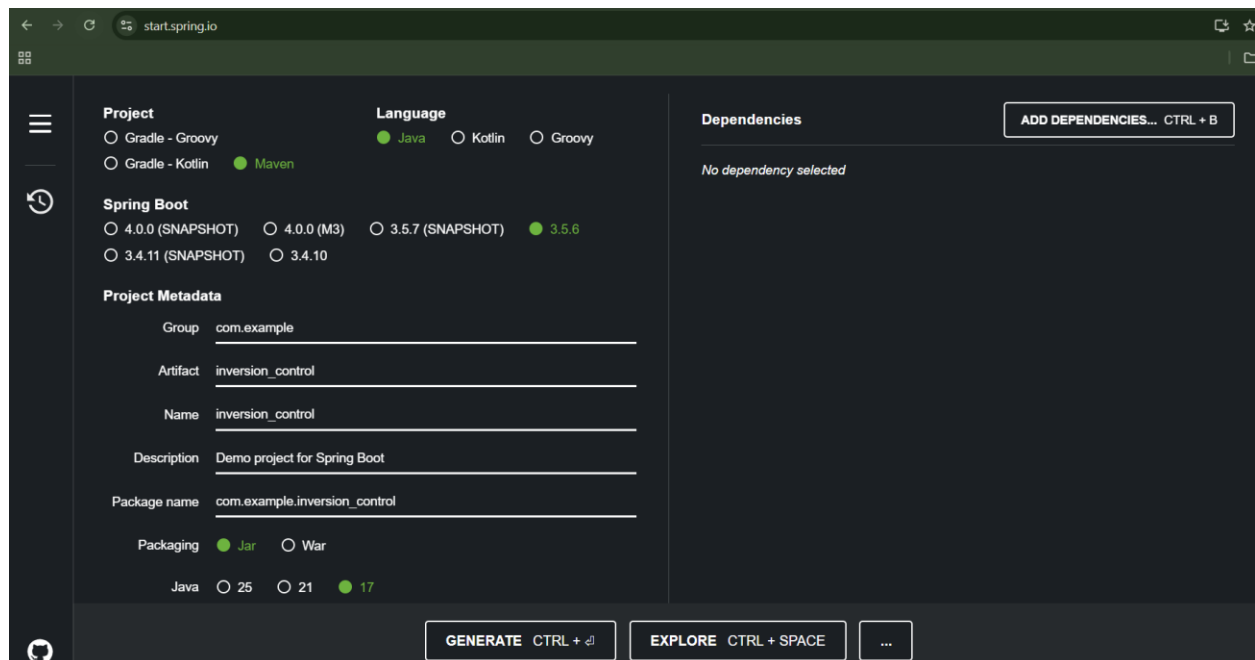

1. Instead of Eclipse, to develop the healthcare application.

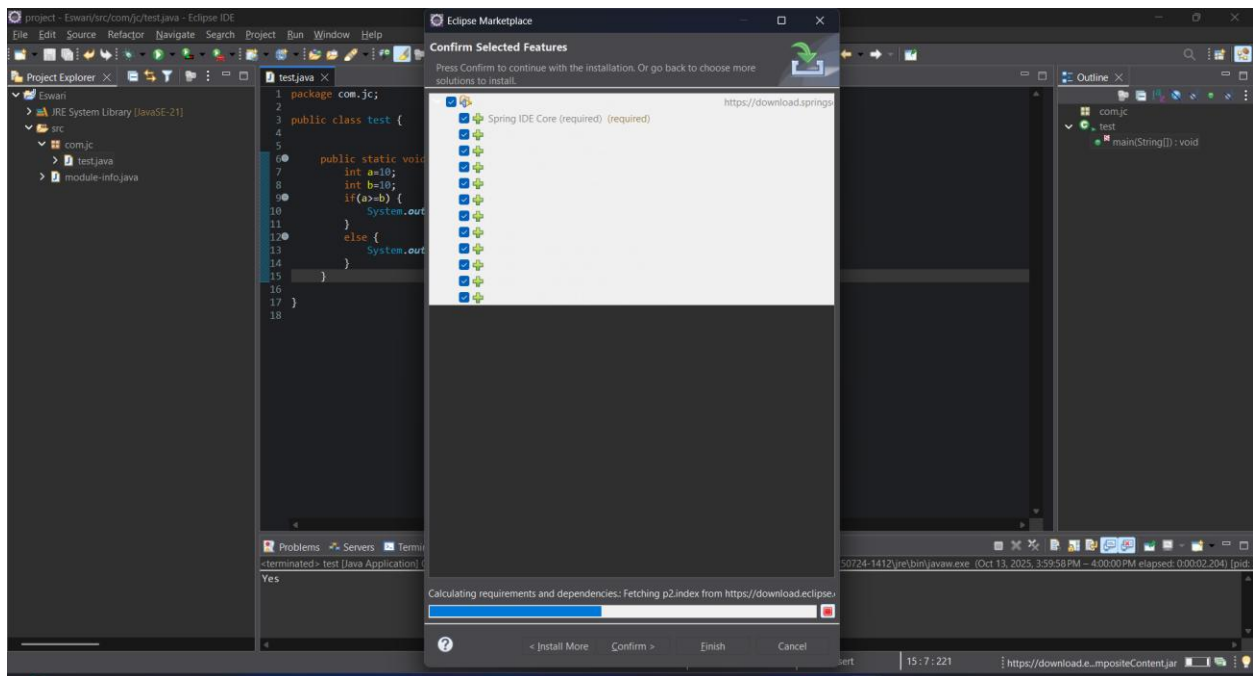

In Eclipse, Java programs are written using classes, methods, variables, loops, and conditional statements. The main method serves as the entry point, and `System.out.println()` displays output on the console.

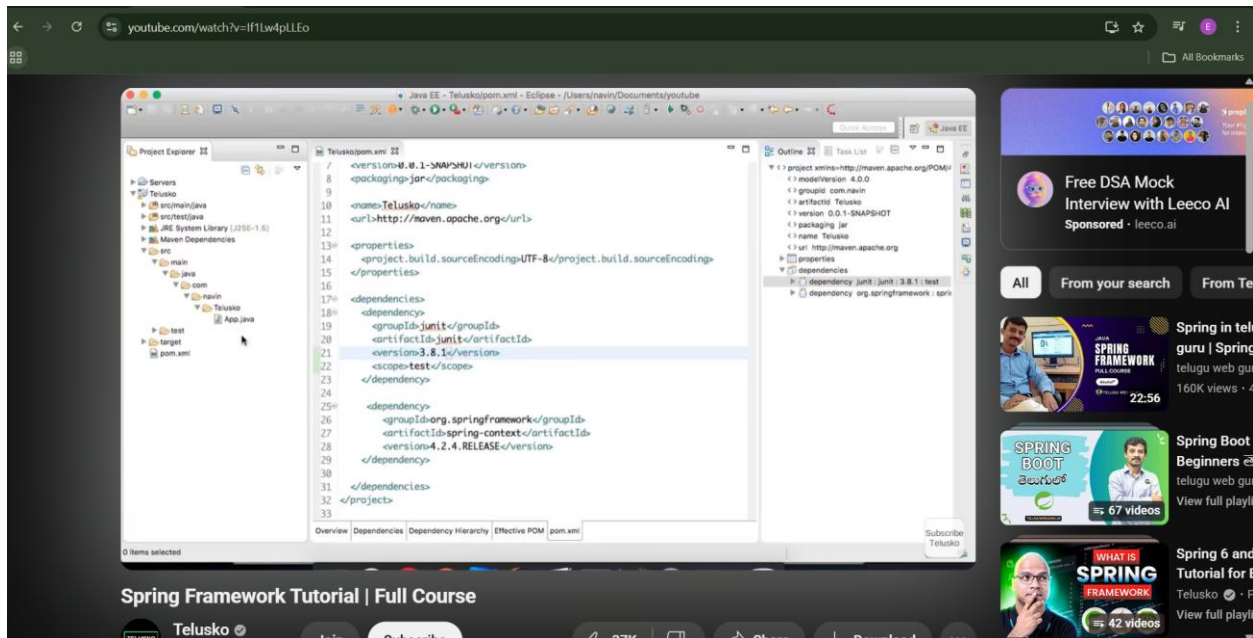

Spring modules can be added manually by downloading the required JAR files and adding them to the project's build path in Eclipse. This allows the project to use Spring classes and features without relying on a build tool like Maven or Gradle.

Spring can be installed in Eclipse by adding the Spring Tool Suite (STS) plugin or by configuring Spring libraries in the project build path.
