To set up the Spring environment, first install Eclipse IDE and configure it for Java development. Download and add the required Spring framework libraries, either by installing the Spring Tool Suite (STS) plugin or manually adding JAR files to the project. Set up the JAVA_HOME environment variable to ensure Java is recognized by Eclipse. Create a sample Spring project or Java class to verify that Spring modules are correctly integrated. This setup allows development of Spring-based applications, enabling features like dependency injection, MVC architecture, and scalable project design.

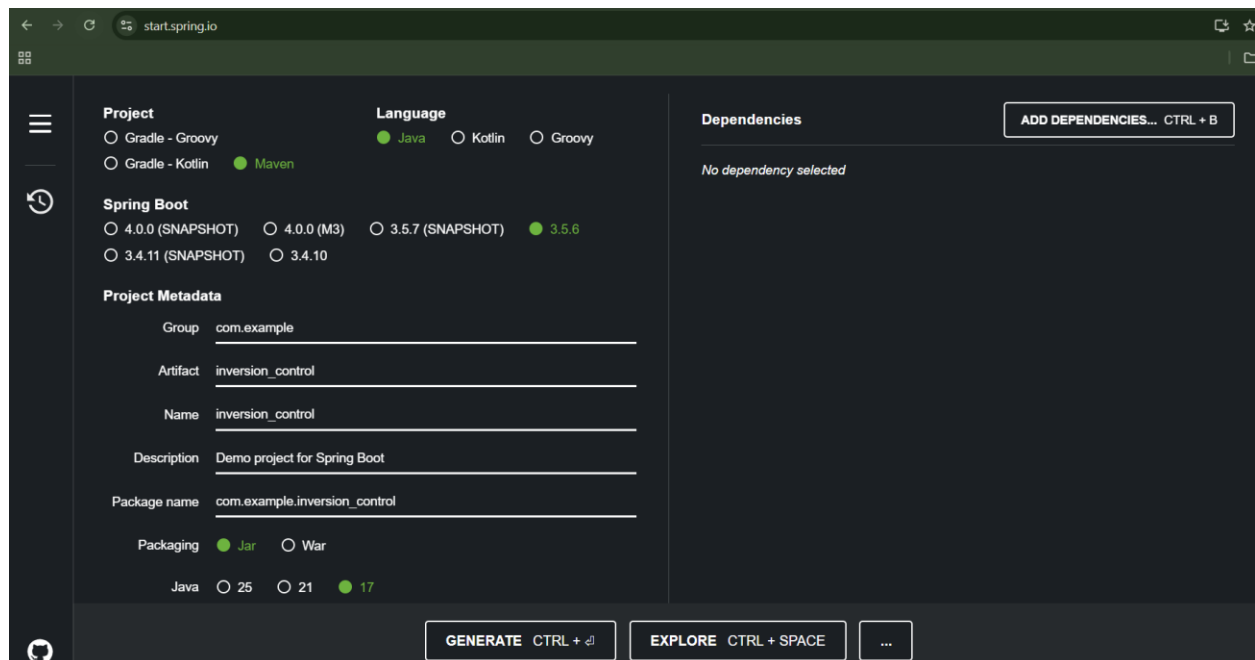

1. Instead of Eclipse, to develop the healthcare application.

In Eclipse, Java programs are written using classes, methods, variables, loops, and conditional statements. The main method serves as the entry point, and `System.out.println()` displays output on the console.

Spring modules can be added manually by downloading the required JAR files and adding them to the project's build path in Eclipse. This allows the project to use Spring classes and features without relying on a build tool like Maven or Gradle.

Spring can be installed in Eclipse by adding the Spring Tool Suite (STS) plugin or by configuring Spring libraries in the project build path.
